

# Web Services

Technology Review

# Background

- Build a distributed computing platform for the Web
- Applications are encapsulated, loosely coupled Web “components” that can bind dynamically to each other
- Easily find these components and integrate them to meet specific requirements
- Plug-and-Play
  - Buy and integrate code into your system
  - Subscribe to necessary services

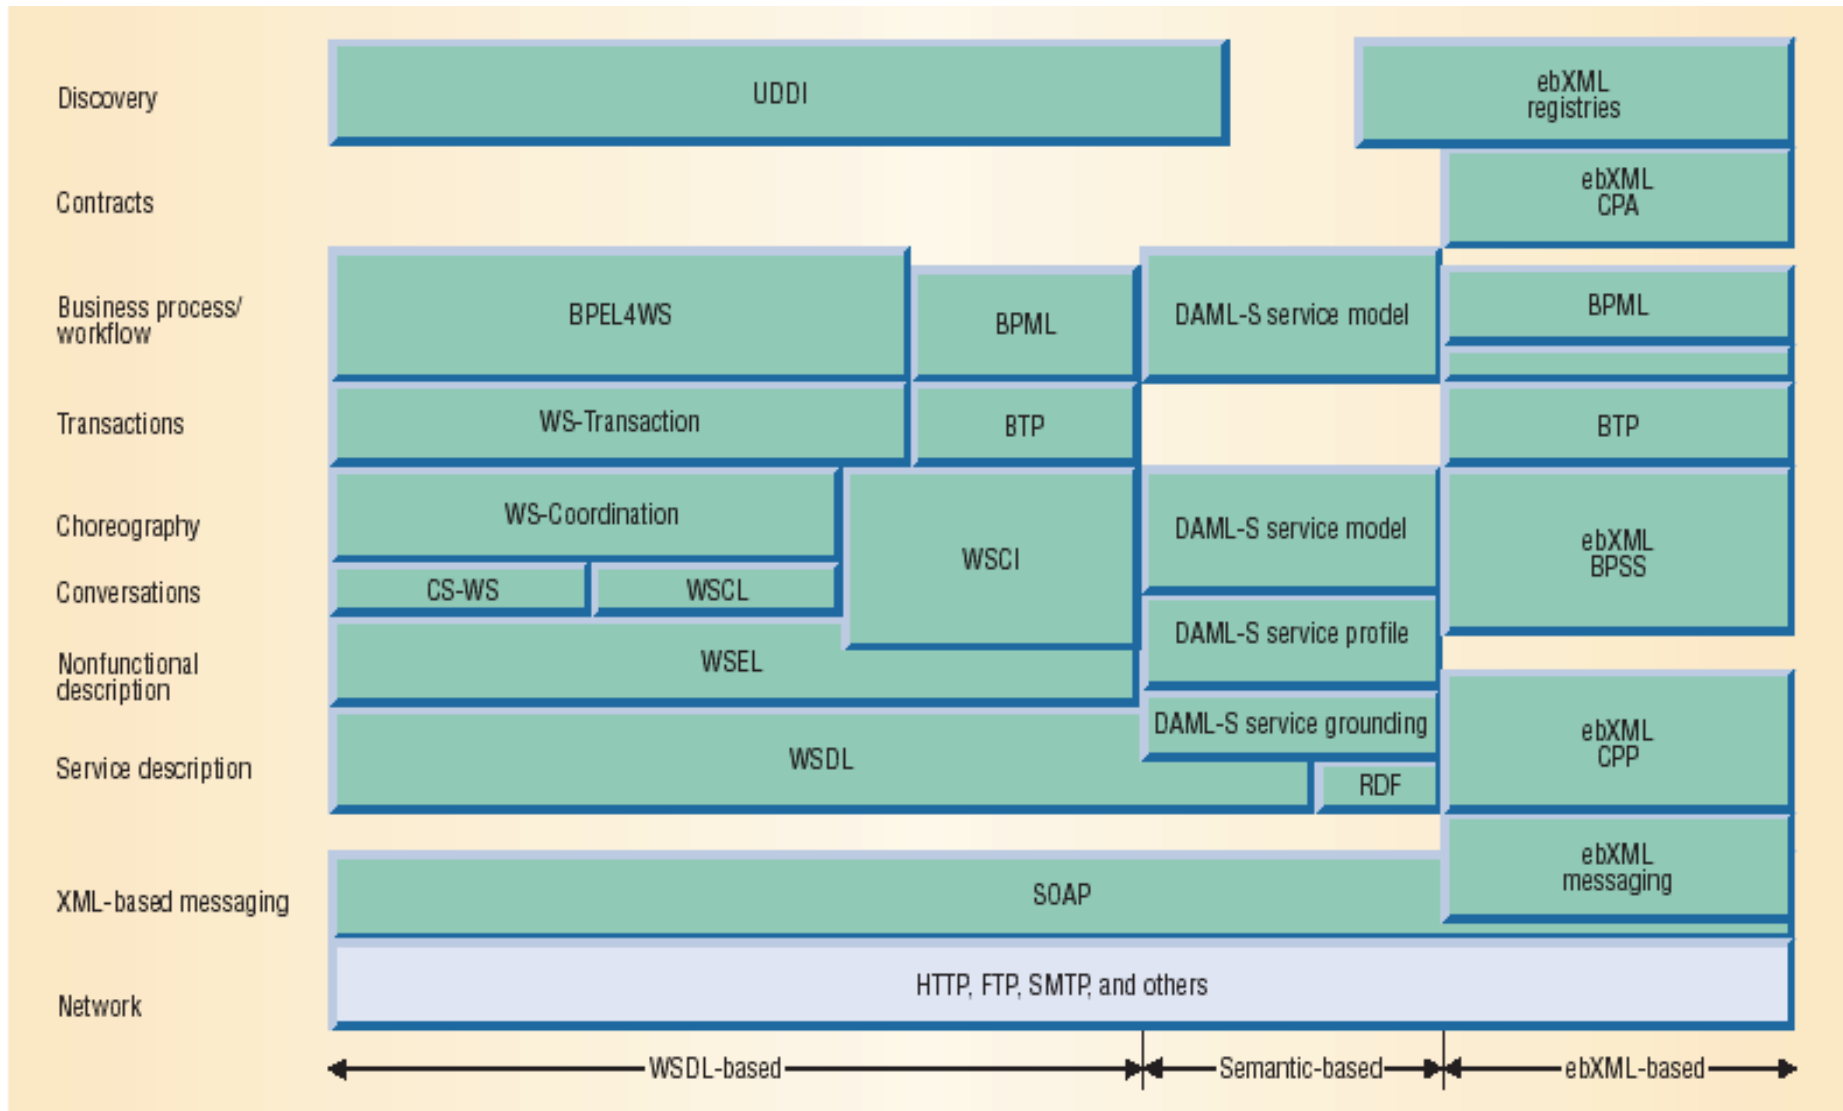

# What are Web Services?

- New breed of Web application
- Self-contained, self-describing, modular applications that can be published, located, and invoked across the Web
- Perform functions, which can be anything from simple requests to complicated business processes
- Once a Web service is deployed, other applications (and other Web services) can discover and invoke the deployed service

# Web Services Standards

- ✦ **UDDI** provides a mechanism for clients to find web services. A UDDI registry is similar to a CORBA trader, or it can be thought of as a DNS service for business applications.
- ✦ **WSDL** defines services as collections of network endpoints or *ports*. A port is defined by associating a network address with a binding; a collection of ports define a service.
- ✦ **SOAP** is a message layout specification that defines a uniform way of passing XML-encoded data. It also defines a way to bind to HTTP as the underlying communication protocol. SOAP is basically a technology to allow for “RPC *over the web*”.

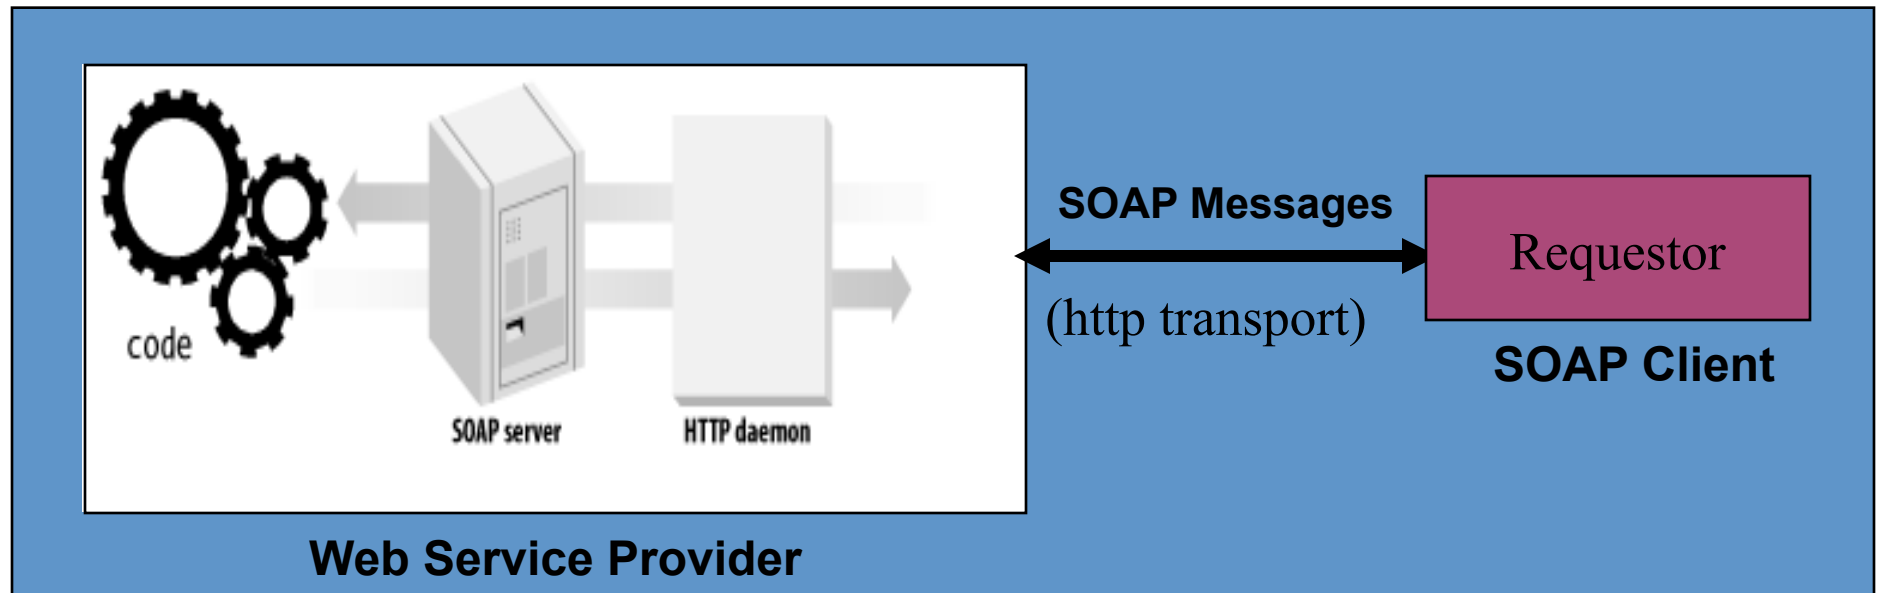

# Web Services Stack (Turner et al., 2003)

# Web services technology stack

- Collection of Web Services standards has been put together and categorized into different levels depending upon their function
- Divided into four levels: protocol, description, interaction and security
- Helps us to understand the purpose of the standards and their underlying assumptions that might be required
- Example: interaction level (CS-WS) presupposes process description level (BPEL4WS), and focuses on exchange of messages based on the order of sequence described in the process description level

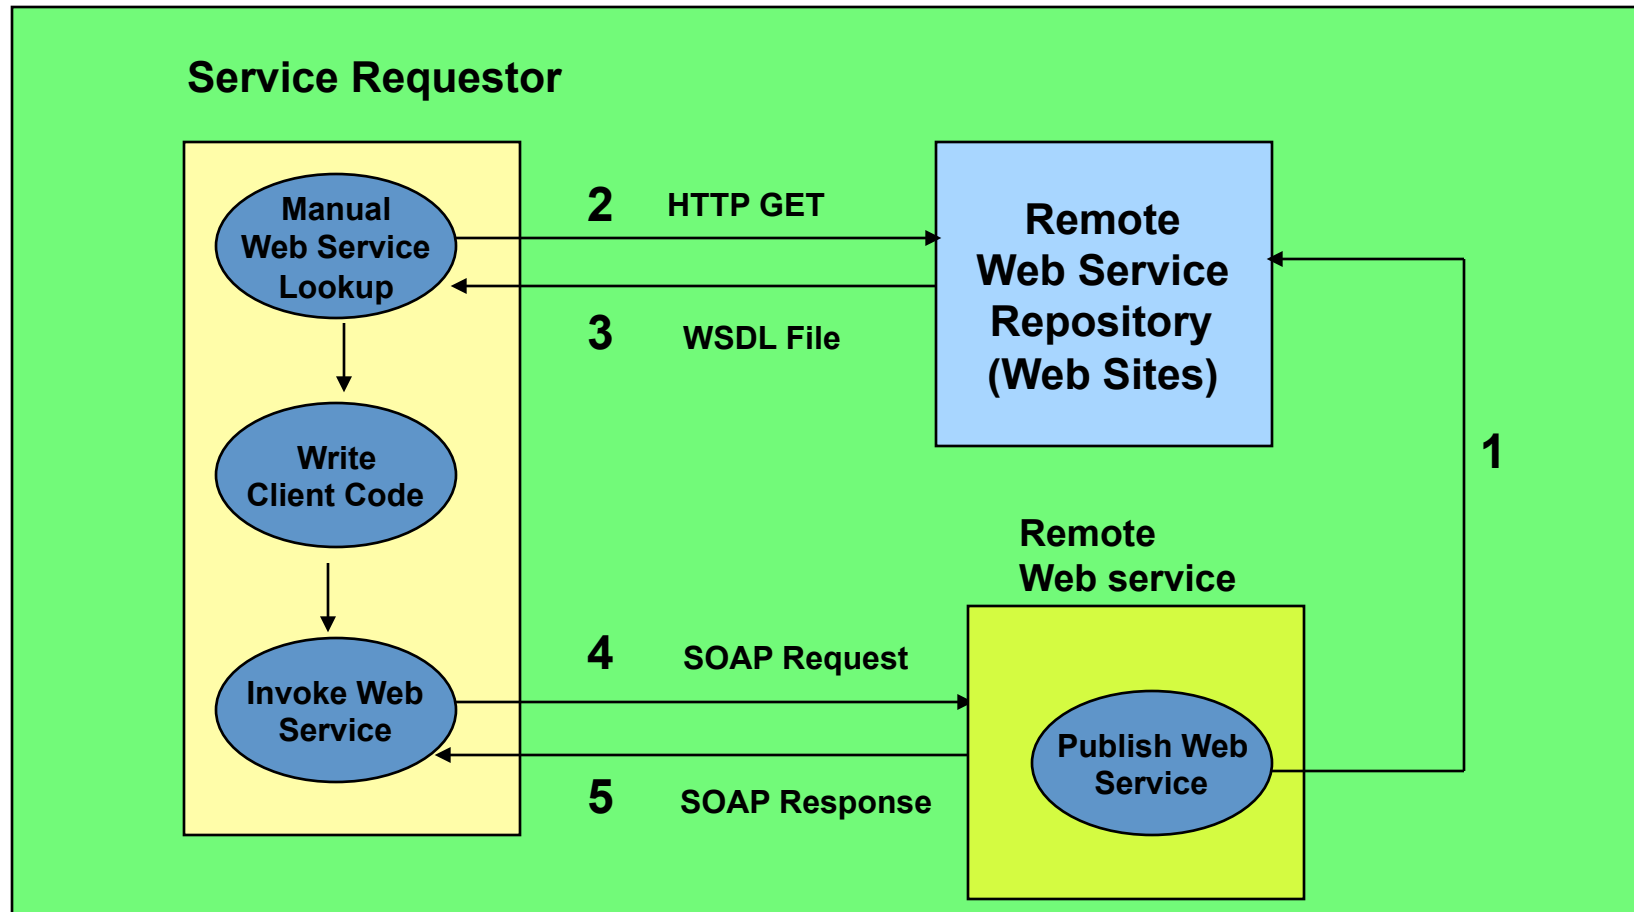

# Web Services: How They Work?

- Components required
  - Software which needs to be exposed as a Web service
  - A SOAP Server (Apache Axis, SOAP::Lite, etc.)
  - HTTP Server (if HTTP is used as the transport level protocol)
  - SOAP Client (Apache Axis, SOAP::Lite etc.)

From S. Chandrasekaran's Talk

# Simple Web Service Invocation

**WSDL** - Web Service Description

**SOAP** - Web Service Message Protocol

# Web Service Message Protocol - SOAP

- SOAP is an XML Messaging Protocol
  - that allows software running on disparate operating systems, running in different environments to make **Remote Procedure Calls (RPC)**.

```
<SOAP:Envelope
  xmlns:SOAP='http://schemas.xmlsoap.org/soap/envelope/'
  SOAP:encodingStyle='http://schemas.xmlsoap.org/soap/encoding/'
  xmlns:v='http://www.topxml.com/soapworkshop/' >

  <SOAP:Header>
    <v:From SOAP:mustUnderstand='1' >
      cdix@soapworkshop.com
    </v:From>
  </SOAP:Header>

  <SOAP:Body>
    <v:DoCreditCheck>
      <ssn>123-456-7890</ssn>
    </v:DoCreditCheck>
  </SOAP:Body>

</SOAP:Envelope>
```

The diagram illustrates the structure of a SOAP message. The XML code is enclosed in a brown border. The `<SOAP:Header>` section is highlighted in light blue, and the `<SOAP:Body>` section is highlighted in light yellow. To the right of the code, two curly braces indicate the structure: the top brace groups the `<SOAP:Header>` section and is labeled **Header**; the bottom brace groups the `<SOAP:Body>` section and is labeled **Body**.

# Web Service Description

- Why describe Web services?
  - A service requestor needs to analyze a service for his requirements
  - A Web service needs to provide the following information
    - the operations it supports
    - the transport and messaging protocols on which it supports those operations
    - the network endpoint of the Web service
- Languages such as WSDL, DAML-S, RDF can be used for describing Web services
  - WSDL – describes the syntactic information of a service
  - DAML-S and RDF – describe the syntactic as well as the semantic information

# WSDL – Web Services Description Language

- Describes the programmatic interface of a web service – similar to IDL
- Two parts of WSDL description:
  - Application-level (abstract interface)
    - Vocabulary, Message, and Interaction
      - data type definitions, operations supported by the service, input/output message formats
  - Specific protocol-dependent details
    - network address, protocol bindings, etc.
      - *what* communication protocol to use
      - *how* to accomplish individual service interactions
      - *where* to terminate communication
    - A port element describes a single end point as a combination of a binding and a network address
    - A service element groups a set of related ports

# Web Service Description (WSDL)

```
<definitions>
```

```
  <types>  
    definition of types..  
  </types>
```

```
  <message>  
    definition of messages...  
  </message>
```

```
  <portType>  
    <operation> ..... </operation>  
    <operation> ..... </operation>  
  </portType>
```

**Abstract  
Description**

```
  <binding>  
    definition of binding....  
  </binding>
```

```
  <service>  
    <port>....</port>  
    <port>....</port>  
  </service>
```

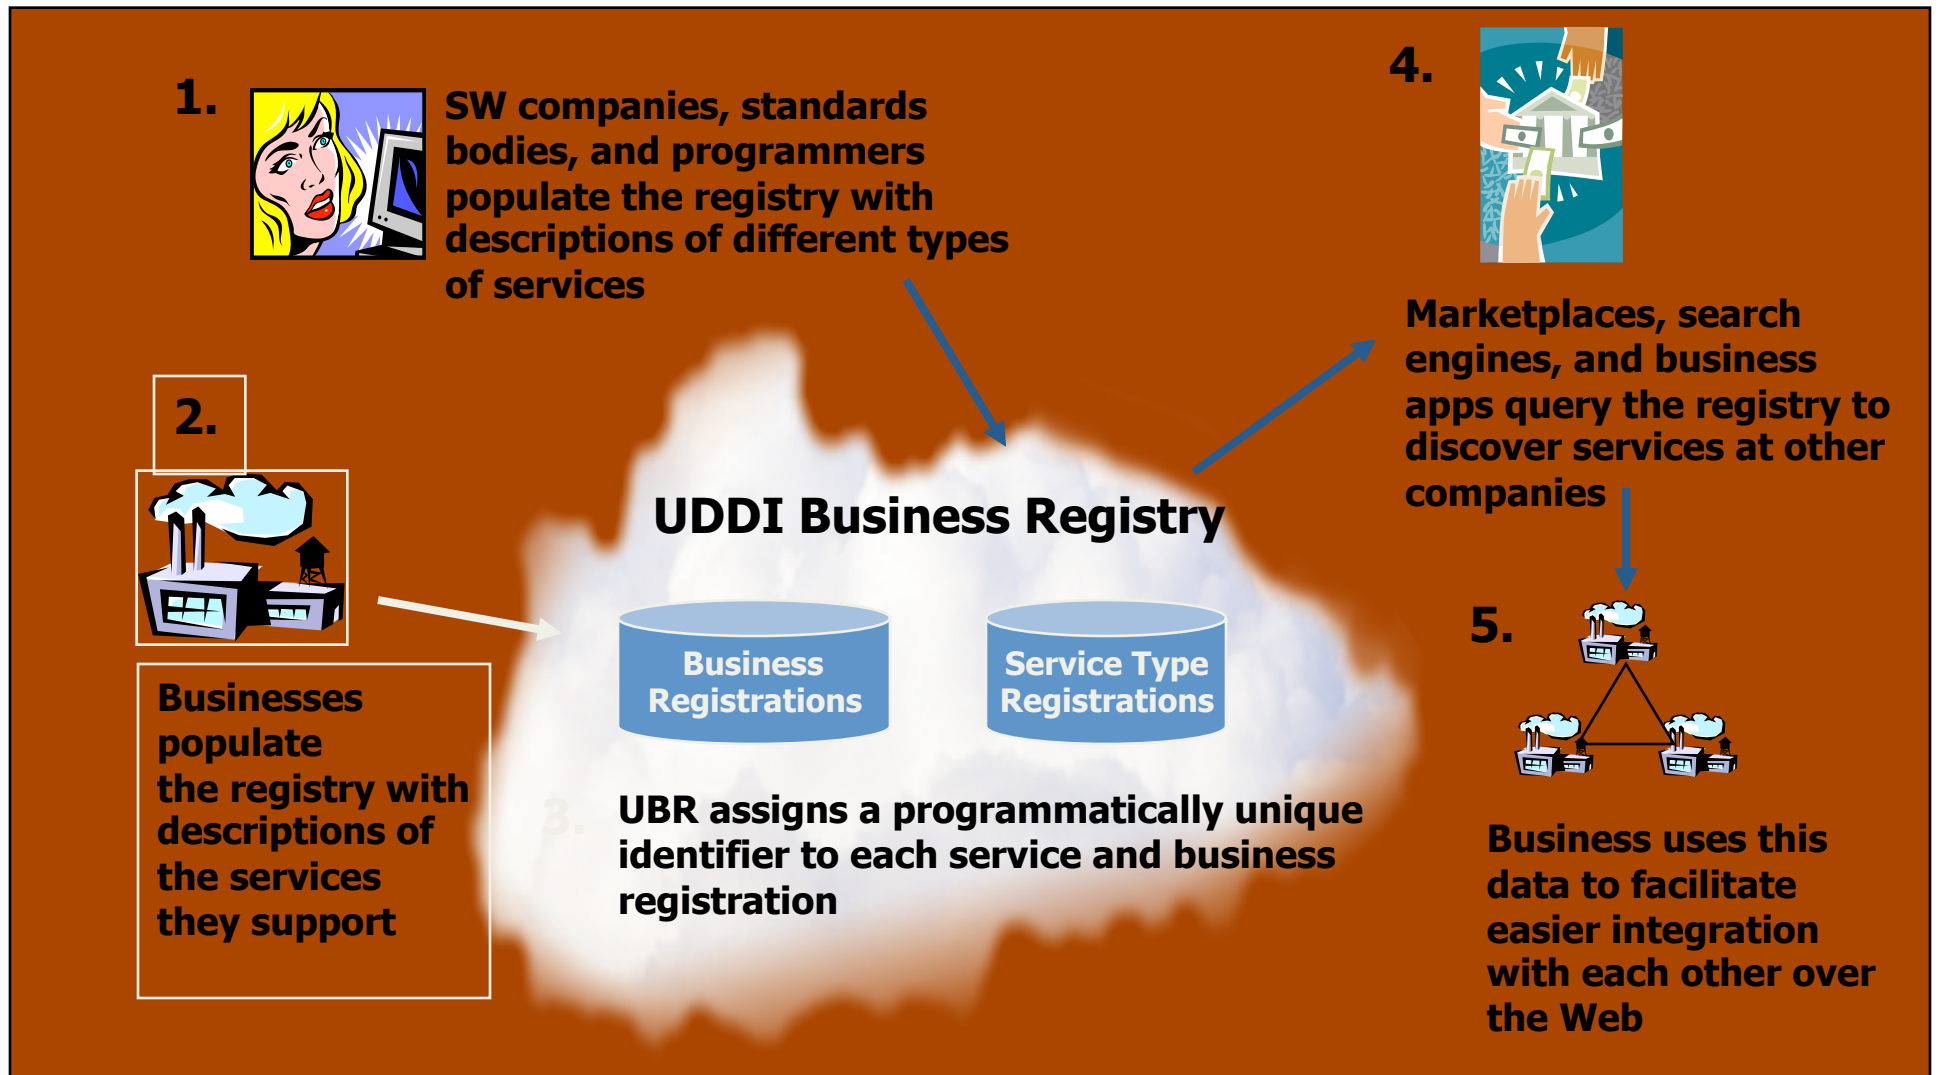

**Concrete  
Description**

```
</definitions>
```

# UDDI – Universal Description, Discovery, and Integration

- Mechanism to register and locate web services
- Interaction with UDDI accomplished via a set of pre-defined SOAP interfaces
- Web services register two types of information within UDDI:
  - tModel (technical model)
    - Abstract service protocols that describe a particular web service's behavior
  - businessEntity
    - Describes the service implementation
    - Refers to multiple tModels and provides descriptions about the behavior of the collection of tModels
